

Module Code & Module Title

CC4057NI Introduction to Information Systems

Assessment Weightage & Type

30% Individual Coursework

Year and Semester

2019-20 Autumn

Student Name: Ishan gurung

Group: n7

London Met ID: np01nt4a190139

College ID: np01nt4a190139

Assignment Due Date: 20 December 2019

Assignment Submission Date: December 20, 2019

I confirm that I understand my coursework needs to be submitted online via Google Classroom under the relevant module page before the deadline in order for my assignment to be accepted and marked. I am fully aware that late submissions will be treated as non-submission and a mark of zero will be awarded.

Introduction

For the second assignment of the course Introduction to information system, we have been given a coursework to create a database about an organization or company of our own choice and in the database, it must contain at least five relation (tables) with at least five different values for each table and five different relationship with each other and each relation must be identified using a suitable primary key and the relations must contains a suitable attributes and for the attributes it constrained using suitable constraints (i.e., unique, not null, auto increment, etc.) and relations must be interlinked using suitable pairing of foreign keys. I have created a database of a restaurant and the procedures of restaurant from manager till to the invoice. By the help of interaction with teachers, friends and from some website I have created ER diagram of the restaurant in which it contains six entity where each of the entity contains at least five attributes which involve in the restaurant, they are listed below;

1. Manager
2. Employee
3. Customer
4. Order
5. Item
6. Invoice

1) Manager: Normally, we understand the manager are those persons of the organization who manages or handle all their staff and the management system of an organization and same as here in my scenario manager is the one who manages all the employee of a restaurant. This entity manager contains five attributes like as name, contact no, manager id, address and email. In the attributes of manager id, it stores the id of manager for unique identification of each manager. So, in the attributes name it stores the name of manager Similarly in the attributes contact no it stores the contact no of manager to contact the manager to call them at the time when the are required. And in the attributes address it stores the address of manager like

city, country etc. and at last the attributes email in which it stores the email of an managers so that we can mail the manager when we required.

2) Employee: Employee are those people who works in the organization. So, in the entity employee there are six attributes which are employee id, address, name, manager id, contact no and email. An attributes employee id of entity employee stores the unique id of an employee which is called primary key and the attributes address stores the address of the employee and in the attributes name it stores the name of an employee in the name column and Similarly in the attributes contact no it stores the contact no of employee to contact the employee to call them at the time when they are required. the attributes email in which it stores the email of an employee so that we can mail the manager when we required. Manager id is an attribute of an employee which is the foreign key of table manager which can identify manager of restaurant.

3) Customer: customer is those persons of any organization who buys goods or item. So, in the entity there are five attributes they are employee id, address, name, customer id, contact no and email. An attributes customer id of entity customer stores the unique id of a customer which is called primary key. and the attributes address stores the address of the customer and in the attributes name it stores the name of an customer in the name column and Similarly in the attributes contact no it stores the contact no of customer to contact the customer to call them at the time when they are required. the attributes email in which it stores the email of a customer so that we can mail the customer when we required. Employee id is an attribute of a customer which is the foreign key of table employee which can identify employee of restaurant.

4) order: order can be defined as those item or goods that are generally requested by the customer so as the scenario I had made. So, the entity order also has five attributes they are order id, name, quantity, date, customer id. An attribute order id of entity order stores the unique id of an order which is called primary key and the attributes order name it stores the name of an order in the order name column. The attributes date stores the date of an orders. The attributes quantity stores the quantity of an order in the order column. Customer id is an attribute of a order which is the foreign key of table customer which can identify order of restaurant.

5)item: an item is generally known as the group of any things so in my scenario items in the restaurant. So, the entity item also has five attributes they are item name, item price, item id, quantity, customer id. An attributes item id of entity item stores the unique id of a item which is called primary key. and the attributes item name it stores the name of an item in the item name column and the attributes item price stores the price of an item in the item price column. The attributes quantity stores the quantity of an item in the item column. Customer id is an attribute of a item which is the foreign key of table customer which can identify item of restaurant.

6) invoice: invoice, I can be defined as a receipt of bill generally which are provided whenever we make any purchase either online or in physical presence of customer. So, the entity invoice also has five attributes they are invoice id, price, amount, quantity, customer id. An attributes invoice id of entity invoice stores the unique id of a invoice which is called primary key. The attributes amount stores the amount in the invoice column. the attributes

price stores the price of an invoice in the item invoice column. The attributes quantity stores the quantity of an invoice in the invoice column. Customer id is an attribute of an invoice which is the foreign key of table customer which can identify invoice of restaurant. Customer is those persons of any organization who buys goods or item. So, in the entity there are five attributes they are employee id, address, name, customer id, contact no and email. An attributes customer id of entity customer stores the unique id of a customer which is called primary key. and the attributes address stores the address of the customer and in the attributes name it stores the name of an customer in the name column and Similarly in the attributes contact no it stores the contact no of customer to contact the customer to call them at the time when they are required. the attributes email in which it stores the email of a customer so that we can mail the customer when we required. Employee id is an attribute of a customer which is the foreign key of table employee which can identify employee of restaurant.

Information system

= Information system, it is the organized system or the collection of human resources and technical which provides the storage, computing, communication, distribution for providing meaningful information. It helps in to analyze the raw data. The collection of hardware, software and some procedure which helps in the collection of data and store them in the meaningful information.

The component of information system are as follows:

- 1) Hardware: the physical technology that works with information system which we can see feel and touch. E.g.: output devices: printer, monitor etc. and input devices: keyboard, mouse etc.
- 2) Software it is the set of programs and the instruction in which it instructs a system to perform task. E.g.: operating system (OS), User interface etc.
- 3) Telecommunication: It is the transmission of sign, signals, information data of any nature by wire, radio, optical fiber, electromagnetic system. It occurs while the exchange of information between communication participants includes the uses of technology.
- 4) Network: It is the network of naming and administration system for smaller another network. It consists of hubs, network devices, and communication media.
- 5) People: It helps to includes tasks such as strategic planning, and budgeting and personnel decision for the information system. It consists of network administrator, devices operator and system specialist.

The classification of information system are as follows:

- 1) Operation support system
- 2) Transaction processing system (TPS)
- 3) Process control system
- 4) Enterprise collaboration system
- 5) Management support system (Zwass, 2013) (Gregersen, 2013)

Database

= Database, it is a collection of tables and information that is organized and also it is an electronic system so that data can be easily accessed, managed and updated. Modern database uses a language called SQL (structured Query Language) which allows user to work with the database. Most well-known database software program are ADABAS, IBM DB2 Microsoft access, Microsoft excel, Microsoft SQL server, MySQL, quick Base. The role of a database in an organization are, it plays an important role in an organization, A maintained database system can run a rapid progress in the organization. It protects the organization data security, because by the use of Login and password for each data it

keeps the organization's data protected. It helps in presentation of data in organization by transforming raw data into information. It helps in the distribution of information and data to the right people at the right time.

Advantage of database are as follows:

1. Independence in data
2. Data sharing.
3. Multiple user can use.
4. User friendly easy to excess.
5. Data about person/product is stored only on time

In my understanding, database is systematic collection of data which helps to reduce time and also makes data management easy to use. It is used to store phone number, contact details and etc. It is the data structure that store information. It contains multiple of table, which includes several different fields. Database management system (DBMS), it is the collection of the programs to access the database in it. It stores the data in the form of column and row so that we can easily see and update the data and access it easily. Database helps to see the detail of the product about the particular things. It helps the organization to see the data of selling the products of their day to day products. (Rouse, 2015) (Anon., 2015)

Relational diagram

(Anon., n.d.)

Database model

We were given to do the database of our own scenario. So, I had made the database of my own scenario which is restaurant. So in the databases there is a six entity in each and they have at least five attributes in each. So the first entity is manager which has five entities they are name,

contact no, manager id, address, email. So in the attributes of manager, manager id is the primary key which gives the unique identification of the manager its data type is in int and it is an auto increment which increases the manager id automatically and it is not null, and in the attributes name of manger it store the name of manager in the datatype varchar which is in null, and in the attributes contact no it stores the contact no of the manger to contact manager when then are required and its datatype varchar and is not null, and the attributes address stores the address of manger when they are required and its datatype is varchar and is not null, and the attributes email stores the email of manager then they are required to mail them whose datatype is varchar which is not null and the manager manages the attributes employee which has six attributes they are employee id, name, address, contact no, email, manager id in which employee id is the primary key of the entity employee which is auto increment which increases the employee id automatically whose datatype is int and it value is not null, and the attributes name of entity employee it stores the name of an employee whose datatype is varchar whose value in null where I don't want to put any value of value null. and the attributes address of entity employee it stores the address of an employee whose datatype is varchar whose value in null where I don't want to put any value of value null. and the attributes contact no of entity employee it stores the contact of an employee whose datatype is varchar whose value in null where I don't want to put any value of value null. and the attributes email of entity employee it stores the mail of an employee whose datatype is varchar whose value in null where I don't want to put any value of value null. and the attributes manager id of entity employee it stores the id of manager in employee attributes whose datatype is varchar whose value in null where I don't want to put any value of value null. The manager id is the foreign key of the attributes manager which references the manager id of the attributes manager table. Customer is those persons of any organization who buys goods or item. So, in the entity there are five attributes they are employee id, address, name, customer id, contact no and email. An attributes customer id of entity customer stores the unique id of a customer which is called primary key whose datatype is int which is not null. and the attributes address stores the address of the customer whose datatype is in varchar which datatype is int and its value is always null and in the attributes name it stores the name of an customer in the name column whose datatype is varchar and its value is always in not null and Similarly in the attributes contact no it stores the

customer no of customer to contact the customer to call them at the time when they are required its datatype is varchar. the attributes email in which it stores the email of a customer so that we can mail the customer when we required and its datatype is varchar and its value is not null. Employee id is an attribute of a customer which is the foreign key of table employee which can identify employee of restaurant and . order can be defined as those item or goods that are generally requested by the customer so as the scenario I had made. So, the entity order also has five attributes they are order id, name, quantity, date, customer id. An attribute order id of entity order stores the unique id of an order which is called primary key and the attributes order name it stores the name of an order in the order name column. The attributes date stores the date of an orders. The attributes quantity stores the quantity of an order in the order column. Customer id is an attribute of a order which is the foreign key of table customer which can identify order of restaurant. item is generally known as the group of any things so in my scenario items in the restaurant. So, the entity item also has five attributes they are item name, item price, item id, quantity, customer id. An attributes item id of entity item stores the unique id of a item which is called primary key. and the attributes item name it stores the name of an item in the item name column and the attributes item price stores the price of an item in the item price column. The attributes quantity stores the quantity of an item in the item column. Customer id is an attribute of a item which is the foreign key of table customer which can identify item of restaurant. : invoice, It can be defined as a receipt of bill generally which are provided whenever we make any purchase either online or in physical presence of customer. So, the entity invoice also has five attributes they are invoice id, price, amount, quantity,

customer id. An attributes invoice id of entity invoice stores the unique id of a invoice which is called primary key. The attributes amount stores the amount in the invoice column. the attributes price stores the price of an invoice in the item invoice column. The attributes quantity stores the quantity of an invoice in the invoice column. Customer id is an attribute of an invoice which is the foreign key of table customer which can identify invoice of restaurant. Customer is those persons of any organization who buys goods or item. So, in the entity there are five attributes they are employee id, address, name, customer id, contact no and email. An attributes customer id of entity customer stores the unique id of a customer which is called primary key. and the attributes address stores the address of the customer and in the attributes name it stores the name of an customer in the name column and Similarly in the attributes contact no it stores the contact no of customer to contact the customer to call them at the time when they are required. the attributes email in which it stores the email of a customer so that we can mail the customer when we required. Employee id is an attribute of a customer which is the foreign key of table employee which can identify employee of restaurant.

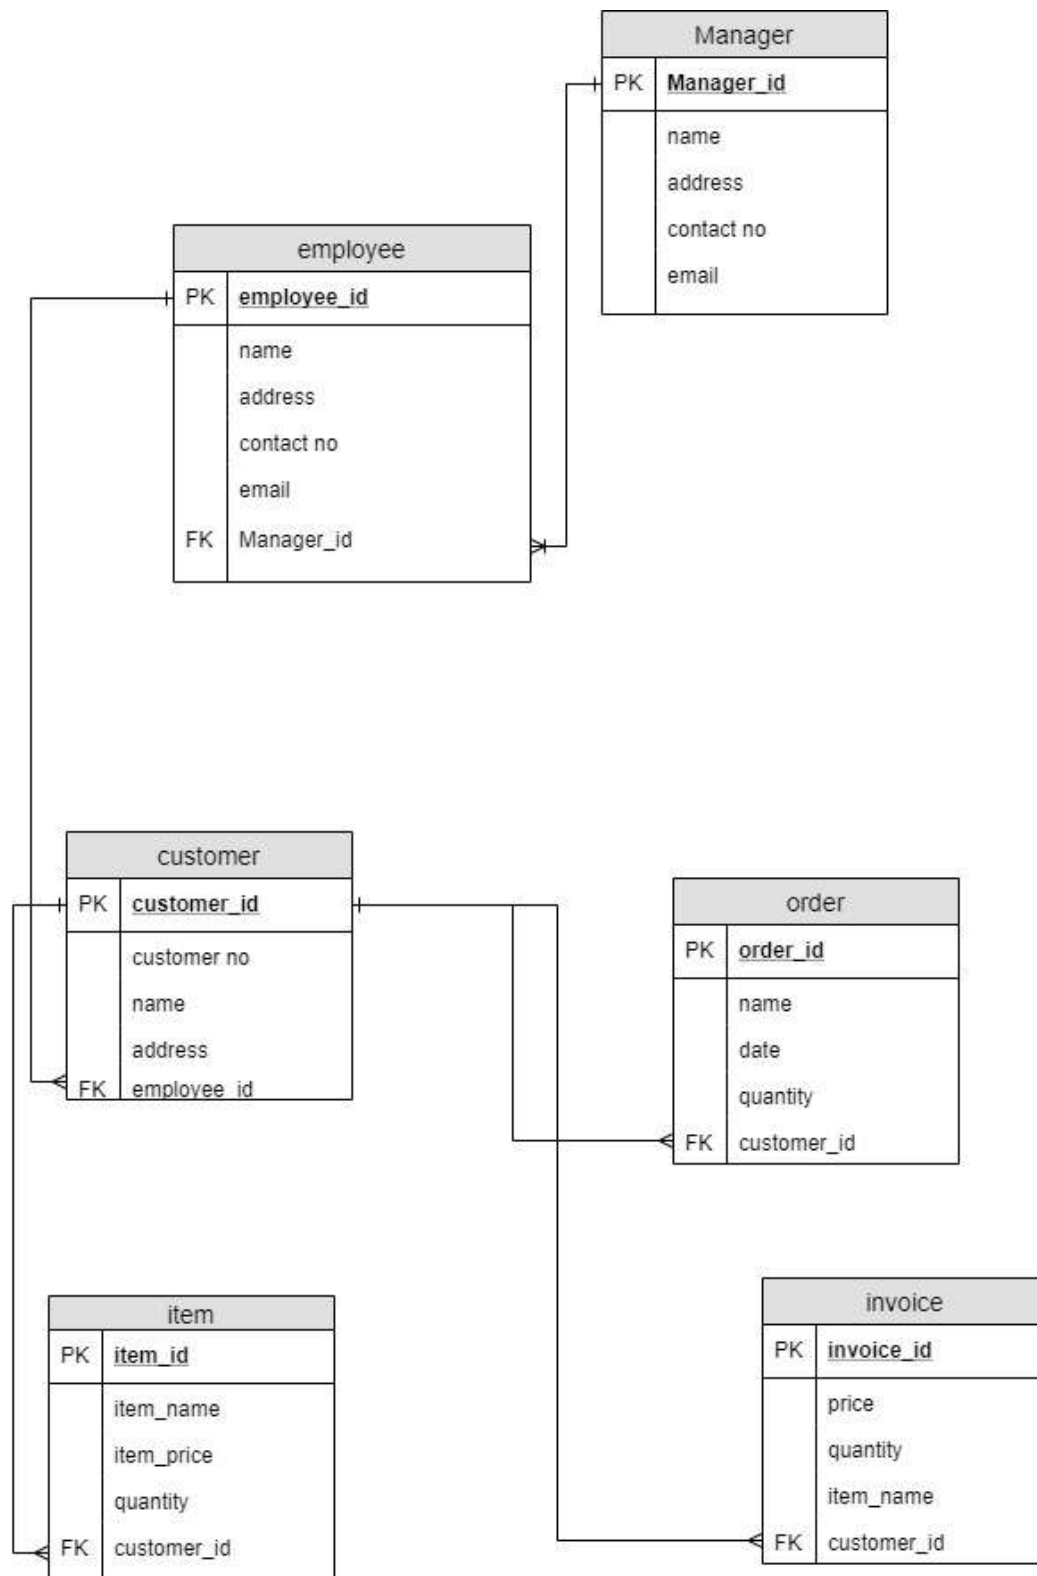

Figure 2relational diagram

1) Manager:

a) Create table manager(manager_id int primary key auto_increment not null, name varchar(255),address varchar(255),contact_no varchar(255),email varchar(255));

```
MariaDB [restaurant]> create table Manager( manager_id int primary key AUTO_INCREMENT ,name varchar(255),address varchar(255), contact_no varchar(255),email varchar(255));
Query OK, 0 rows affected (0.137 sec)
```

Figure 3create table manager

```
MariaDB [restaurant]> desc manager;
```

Field	Type	Null	Key	Default	Extra
manager_id	int(11)	NO	PRI	NULL	auto_increment
name	varchar(255)	YES		NULL	
address	varchar(255)	YES		NULL	
contact_no	varchar(255)	YES		NULL	
email	varchar(255)	YES		NULL	

```
5 rows in set (0.006 sec)
```

Figure 4manager SQL

Inserting the value of manager table.

Insert into manager values
(11,"ram","sinamangal",9812356756,ram.gurung1@gmail.com)

```

MariaDB [restaurant]> insert into Manager values(12,"gita","baneshower","9812354556","gita.gurung1@gmail.com");
Query OK, 1 row affected (0.004 sec)

MariaDB [restaurant]> insert into Manager values(13,"shyam","lalitpur","9812354558","shyam1@gmail.com");
Query OK, 1 row affected (0.003 sec)

MariaDB [restaurant]> insert into Manager values(14,"ishan","patan","9862354558","ishan1@gmail.com");
Query OK, 1 row affected (0.003 sec)

```

Figure 5 insert values in manager

```

MariaDB [restaurant]> select *from manager;;
+-----+-----+-----+-----+-----+
| manager_id | name | address | contact_no | email |

Data dictionary

Manager

Entity name	Entity description	Column name	Column description	Data type	Length	Primary key	Foreign key	Nullable	Unique	notes
Manager	A manager is someone who manages the resources in the restaurant.	Manager id	This column store id of manager for unique identification of each manager	int		True	false	false	True	Auto increment increases the number of manager id automatically
		Name	This column stores name of the manager	varchar	255	False	false	False	False	
		address	This column stores address of manager	varchar	255	False	False	False	False	
		Contact no	This column stores contact no of manager	varchar	255	False	False	False	False	
		email	This column store email of the manager	varchar	255	False	false	false	false	

Table 1MANAGER

Table 2 EMPLOYEE

Entity name	Entity description	Column name	Column description	Data type	length	Primary key	Foreign key	Nullable	Unique	notes
Employee	An employee is one who deals with the customer	Employee id	This column stores id of employee for uniquely identification of each employee	Int		true	False	False	true	Auto increment increases the number of employee id automatically
		Name	This column stores name of an employee	Varchar	255	False	False	False	False	
		Address	This column stores address of an employee	Varchar	255	False	False	False	False	
		Contact no	This column stores contact no of an employee	Varchar	255	False	False	False	False	
		Email	This column stores email of an employee	int		False	false	False	False	
		Manager id	This column stores manager id	int		false	true	False	true	It is references of manager if from

			of an employee							manager table in employee column
--	--	--	-------------------	--	--	--	--	--	--	---

Entity name	Entity description	Column name	Column description	Data type	Length	Primary key	Foreign key	Nullable	Unique	notes
Customer	A customer is one who makes different order to the restaurant	Customer id	This column stores the id of customer in it.	Int		True	false	False	True	An auto increment increases the number of customer id automatically
		Customer no	This column stores no of the customer in it.	Varchar	255	False	False	False	False	
		Name	This column stores name of the customer in it.	Varchar	255	False	False	False	False	
		Address	This column stores the address of	Varchar	255	False	False	False	False	

			the customer in it.							
		Employee id	This column stores the id of employee in the customer table	int		false	True	False	false	It references employee from employee table customer column

Table 3CUSTOMER

Table 4ORDER

Entity name	Entity description	Column name	Column description	Datatype	Length	Primary key	Foreign key	Nullable	Unique	notes
Orders	an order is one where the customer gives the order to the restaurant	Order id	This column stores the order's in it.	Int		True	False	False	True	An auto increment increases the number of order id automatically
		Name	This column stores the name of order in it.	Varchar	255	False	false	False	False	
		Date	This column stores the date of order in it.	Int		False	False	False	False	
		Quantity	This column stores the quantity of orders in it.	Int		False	False	False	False	
		Customer id	This column stores the id of customer	Int		false	True	False	False	It is references of customer id from orders table in

			in orders table.							employee column
--	--	--	---------------------	--	--	--	--	--	--	--------------------

Conclusion

After the completion of this coursework, I conclude that we have learned how an organization handles data and databases are stored organization in the business form. We have learned how to make an databases of an organization and also I have learned different databases software for creation of the data storing , modifying, and how tho relate multiple databases using single column as foreign key. I have learned to make data unique ,and how to create ER diagram, to make relational diagram and many more. Also I have learned to make data dictionary , databases queries and how to give citation, how to reserch from the online source and make the report and coursework with the help of various tools like xampp, draw.io, creatly, websites.
